# {lambda talk}

# Alain Marty Engineer Architect Villeneuve de la Raho, France marty.alain@free.fr

## **ABSTRACT**

The {lambda way} project is a web application built on two engines, {lambda talk} and {lambda tank}. {lambda talk} is a purely functional language unifying authoring, styling and scripting in a single and coherent Lisp-like syntax, working in {lambda tank}, a tiny wiki built as a thin overlay on top of any web browser. In this paper we forget {lambda tank}, mainly a PHP engine managing text files on the server side, and progressively introduce {lambda talk}, a Javascript engine evaluating code in realtime on the client side. The making of {lambda talk} is done in three stages:

- 1) we define the minimal set of rules making {lambda talk} a programming language, complete even if unusable,
- 2) we progressively add numbers, operators, data and control structures making {lambda talk} *more usable*,
- 3) we finally build on the browsers' full functionalities a set of *libraries* making {lambda talk} usable and much more efficient.

As a guilding line, at each stage, we compute with a total precision the factorial of **5** and **50**:

```
5! = 120
50! = 30414093201713378043612608166064
768844377641568960512000000000000
```

In a last section, APPENDICE, some explanations are given on the {lambda talk}'s Javascript implementation.

- Theory of computation~Regular languages
- Theory of computation~Lambda calculus
- Software and its engineering~Functional languages
- Software and its engineering~Extensible Markup Language (XML)

### INTRODUCTION

{lambda talk} expressions are written in an editor frame, evaluated in real time and displayed in the wiki's viewer frame, then saved and published on the WEB. « A wiki is a web application which allows collaborative modification, extension, or deletion of its content and structure. [1] » The father of this concept, Ward Cunningham [2], gives a simple and clear introduction to {lambda talk}:

• 1) Away from curly braces {} words are just words:

```
Hello World! -> Hello World!
```

• 2) Expressions are written in a *prefix notation*:

```
2+3 is equal to {b {+ 2 3}}
-> 2+3 is equal to 5
```

• 3) Functions are created with *lambda* and named with *def*:

These examples use the "+" Math operator, the "b" HTML/CSS markup operator and Javascript numbers. In the following we want to introduce {lambda talk} built upon the *deepest foundation* possible, *simple words*, and we will ignore everything but words until the third section.

### 1. WORDS

We present the structure and evaluation of a {lambda talk} expression.

## 1.1. expressions

{lambda talk} is mainly built on three rules freely inspired by the  $\lambda$ -calculus<sup>[3]</sup>. An expression is defined recursively as follows:

```
expression is [word|abstraction|application]*
```

#### where

An expression is made of words, abstractions and applications where 1) a word is any character except spaces "\s" and curly braces "{}", 2) an abstraction is the "process" (called a function) selecting a sequence of words (called arguments) in an expression (called body), 3) an application is the "process" calling an abstraction to replace selected words by some other words (called values).

The evaluation follows these rules:

- 1. words are not evaluated,
- 2. abstractions are evaluated before applications,
- 3. an abstraction is evaluated to a single word, a reference to an anonymous a function stored in a global dictionary,

initially empty,

- 4. an application is progressively evaluated from inside out, to a sequence of words,
- 5. the evaluation stops when all expressions have been reduced to a sequence of words.

What can we do with that?

```
1.1.1. words
```

```
Hello World -> Hello World
```

Words are not evaluated and are displayed as they are.

#### 1.1.2. abstraction

```
{lambda {o a} oh happy day!}
-> _LAMB_1
```

The abstraction selects o and a as characters whose occurences in the expression oh happy day! are to be replaced by some future values, and returns the reference to an anonymous function.

```
1.1.3. application <sup>(1)</sup>
```

```
{{lambda {o a} oh happy day!} o000o aaAAaa} -> o000oh haaAAaappy daaAAaay!
```

The abstraction is defined and immediately called. The abstraction is first evaluated to a word, say \_LAMB\_10, the application {\_LAMB\_10 o0000 aaAAaa} gets the given values, calls the abstraction which makes the substitution and returns the result, o0000h haaAAaappy daaAAaay!.

# 1.1.4. application (2)

```
{{lambda {z}
{z {lambda {x y x}}}
{{lambda {x y z}
{z x y}} Hello World}}
-> Hello

{{lambda {z}
{z {lambda {x y y}}}
{z {lambda {x y z}
{z x y}} Hello World}}
-> World
```

These expressions return respectively the first and the second words of Hello World. This is very similar to a pair and its accessors. Let's trace the evaluation leading to Hello:

• 1) Nested lambdas are first evaluated:

• 2) Then simple forms are evaluated:

```
1: {_LAMB_3 {_LAMB_2 Hello World}}
2: {_LAMB_3 {{lambda {x y z} {z x y}}} Hello
```

```
World}}
```

{{lambda {x y z} {z x y}} Hello World} is a partial application replacing "x" and "y" by "Hello" and "World", creating a new lambda waiting for the third value, {lambda {z} {z Hello World}}, and returning a reference, LAMB 4.

```
3: {_LAMB_3 _LAMB_4}
4: {{lambda {z} {z _LAMB_1}} _LAMB_4}
5: {_LAMB_4 _LAMB_1}
6: {{lambda {z} {z  Hello World}} _LAMB_1}
7: {_LAMB_1  Hello World}
8: {{lambda {x  y}  x}  Hello World}
9: Hello
```

To sum up on lambdas:

- 1) lambdas are first class functions,
- 2) lambdas accept partial function application: a lambda called with a number of values lesser than their arity memorizes the given values and returns a new lambda waiting for the rest.
- 3) lambdas *don't create closures*, inner lambdas have no access to outer lambdas' arguments, there is no lexical scoping, no environment, no free variables.

Lambdas are pure black boxes, independant of any context, as are mathematical functions.

# 1.1.5. application <sup>(3)</sup>

```
{{lambda {n} {{lambda {g n} {g g n}} {lambda {g n} {{lambda {p t f g n} {{lambda {x y z} {z x y}} t f}} g n}} {lambda {n} {{lambda {x y z} {z x y}} t f}} g n}} {lambda {n} {{lambda {x, y z}}} {z x y}} t f}} g n}} {lambda {z, {z {lambda {x, y y}}}} {lambda {z} {z {lambda {x y} x}}}} n}} {lambda {z} {z {lambda {x y} x}}} n}} {lambda {g n} {{lambda {f x, y}} {lambda {f x, y}}} {lambda {g n} {{lambda {n m f} {m {n f}}}} n {g g {{lambda {n} {{lambda {x y} z}} {z x yz}} {{lambda {z, y z} {z x y}}} {{lambda {z, y z} {z x y}}} {{lambda {z, y z} {z x y}}} {{lambda {x y} y}} p}} {{lambda {x y y}}} p}} {{lambda {x y z} {z x y}} {{lambda {f x, y x}} {{lambda {x y} y}}} n}}} {{lambda {f x, y x}}} {{lambda {f x, y x}} {{lambda {f x, y x}}} n}}} } {{lambda {f x, y x}} n}}} } n}}}} } } } } } } } } } }
```

At this point, you should believe that this unreadble expression evaluated to an anonymous function is the factorial of 5, 5! = 120, computed using its recursive definition:

```
fac(n) = 1 if n == 0 else fac(n) = n*fac(n-1)
```

#### 1.2. names

In order to make code more readable we introduce a second special form {def word expression}, with which we will populate the *global dictionary* with *constants* and give *names* to anonymous functions. Let's rewrite with names the previous examples.

### 1.2.1. words

Any sequence of words can be given a name:

```
{def HI Hello World}
-> HI

{HI}
-> Hello World
```

Note that the word HI is not evaluated out of curly braces {}. Note that, in a spreadsheet, one write =PI() to get the value associated to PI.

#### 1.2.2. abstractions

An anonymous functions can be given a name:

```
{def GOOD_DAY {lambda {:o :a} :oh h:appy day!}}
-> GOOD_DAY
```

# 1.2.3. application <sup>(1)</sup>

making applications easier:

```
{GOOD_DAY oOOOo aaAaa}
-> oOOOoh haaAaappy day!

{GOOD_DAY ♠ ♥}
-> ♠h h♥ppy day!
```

Note: arguments and their occurences in the function's body have been prefixed with a colon ":". Doing so prevents unintentional substitutions in the function's body, for instance the word day hasn't been replaced by daaAaay or d ♥ y. Escaping/marking arguments, for instance prefixing them with a colon ":", is highly recommended if not always mandatory. We will do it systematically and we add this constraint to the previous rules: « In lambda expressions arguments arg must at least be tagged by some escaping character, for instance :arg, or for a better security, bracketted between two, for instance :arg:.

# 1.2.4. application <sup>(2)</sup>

```
{def CONS {lambda {:x :y :z} {:z :x :y}}}
-> CONS
{def CAR {lambda {:z} {:z {lambda {:x :y} :x}}}}
-> CAR
{def CDR {lambda {:z} {:z {lambda {:x :y} :y}}}}
-> CDR

{CAR {CONS Hello World}}
-> Hello
{CDR {CONS Hello World}}
-> World
```

In fact we just have built and used *pairs* and its *accessors*. Where  $LISP^{[4]}$  and  $SCHEME^{[5]}$  use a closure

```
(def cons (lambda (x y) (lambda (z) (z x y))))
(def car (lambda (z) (z (lambda (x y) x))))
(def cdr (lambda (z) (z (lambda (x y) y))))
```

{lambda talk} uses partial application. There is no outer environment storing accessible values, values are stored inside lambdas.

```
1.2.5. application <sup>(3)</sup>
```

We rewrite the example 1.1.5. using two names:

```
{def FOO {lambda {:n} {{lambda {:g :n} {:g :g
:n}} {lambda {:g :n} {{lambda {:b :t :f :g :n}
{{{:b :n} {{lambda {:x :y :z} {:z :x :y}} :t
{lambda {:x} {lambda {:z} {:z {lambda {:x :y}
:y}}}  {lambda {:z} {:z {lambda {:x :y} :x}}}}
:n}} {lambda {:g :n} {{lambda {:n :f :x} {:f
{\{:n : f\} : x\}} {lambda {:f :x} :x}}} {lambda {:g
:n} {{lambda {:n :m :f} {:m {:n :f}}} :n {:g :g
{{lambda {:n} {{lambda {:z} {:z {lambda {:x :y}}
:x}}} {{:n {lambda {:p} {{lambda {:x :y :z} {:z}
:x :y}} {{lambda {:z} {:z {lambda {:x :y} :y}}}
:p} {{lambda {:n :f :x} {:f {{:n :f} :x}}}
{\{\{lambda \{:z\} \{:z \{lambda \{:x :y\} :y\}\}\} :p\}\}\}\}}
{\{\{lambda \{:x :y :z\} \{:z :x :y\}\}\}} {\{lambda \{:f :x\}\}}
:x} {lambda {:f :x} :x}}}} :n}}} :g :n}} :g
-> FOO
{def BAR
{lambda {:f :x} {:f {:f {:f {:f :x}}}}}}
(FOO BAR )
-> _LAMB_8
```

We notice that FOO is applied to BAR, an anonymous function applying 5 times: f to:x. We can now better understand that the result is a reference to an anonymous function which could be associated to the factorial of 5. And we guess that applying 50 times: f to:x would lead to an anonymous function associated to the factorial of 50 ... provided we had a huge memory and thousands years before us!

Concluding this first section we note that, until now, {lambda talk} knows nothing but text substitution and that the dictionary contains no built-in primitive. In the following section, *still without using any Javascript Math object*, we progressively build **numbers**, **operators**, **data** and **control structures** to compute 5! and 50!.

### 2. NUMBERS

Following "Collected Lambda Calculus Functions" [6] we progressively add numbers, operators, data and control structures.

#### 2.1. numbers

We define the so-called *Church numbers*:

```
{def ZERO
          {lambda {:f :x} :x}}
-> ZERO
{def ONE
          {lambda {:f :x} {:f :x}}}
-> ONE
          {lambda {:f :x} {:f {:f :x}}}}
{def TWO
-> TWO
{def THREE {lambda {:f :x} {:f {:f :x}}}}}
-> THREE
{def FOUR
          {lambda {:f :x} {:f {:f {:f
:x}}}}
-> FOUR
          {lambda {:f :x} {:f {:f {:f {:f
{def FIVE
:x}}}}}
-> FIVE
```

Applied to a couple of any words, we get strange things:

```
{ZERO . .} -> .

{ONE . .} -> (. .)

{TWO . .} -> (. (. .))

{FIVE . .} -> (. (. (. (. (. .)))))
```

We define the function CHURCH which translates Church numbers in a more familiar shape:

**Note:** the CHURCH function is built on a primitive function, '+' and on the Javascript number primitive, which are not supposed to exist at this point. Consider that it's only for readability.

## 2.2. operators

Based on Church numbers, which are **iterators by themselves**, we can easily define and test a first set of operators:

```
{def SUCC {lambda {:n :f :x} {:f {{:n :f} :x}}}}
-> SUCC
{def ADD {lambda {:n :m :f :x} {{:n :f} {{:m :f}}
:x}}}
-> ADD
{def MUL {lambda {:n :m :f} {:m {:n :f}}}}
-> MUT.
{def POWER {lambda {:n :m} {:m :n}}}
-> POWER
{CHURCH {SUCC ZERO}}
                           -> 1
                            -> 2
{CHURCH {SUCC ONE}}
{CHURCH {SUCC THREE}}
                           -> 3
{CHURCH {ADD TWO THREE}}}
                           -> 5 // 2+3
                           -> 6 // 2*3
{CHURCH {MUL TWO THREE}}
{CHURCH {POWER THREE TWO}} -> 9 // 3^2
```

Building "opposite" functions like PRED, SUBTRACT, DIVIDE is not so easy - and Church himself avoided them in the primitive version of  $\lambda$ -calculus. The answer was given by Stephen Cole Kleene<sup>[7]</sup>, the father of Regular Expressions: *Church numbers can be used to iterate and pairs to aggregate*. This is how:

- we define a function PRED.PAIR getting a pair [a,a] and returning a pair [a,a+1],
- the function PRED computes n iterations of PRED.PAIR starting on the pair [0,0] and leading to the pair [n-1,n] and returns the first, n-1:

```
{def PRED.PAIR {lambda {:p}
    {CONS {CDR :p} {SUCC {CDR :p}}}}}
-> PRED.PAIR
{def PRED {lambda {:n}
    {CAR {{:n PRED.PAIR} {CONS ZERO ZERO}}}}}
-> PRED

{CHURCH {PRED FIVE}}
-> 4
```

## 2.3. « To Iterate is Human, ...

We already have all what is needed to evaluate complex expressions like 1\*2\*3\*...\*n. Remembering the PRED operator:

- we define a function ITER.PAIR getting a pair [a,b] and returning a pair [a+1,a\*b],
- the function ITER computes n iterations of ITER.PAIR, starting on the pair [1,1] and leading to the pair [n,n!] and returns the second.n!

```
{def ITER
{def ITER.PAIR
    {lambda {:p}
        {CONS {SUCC {CAR :p}}
        {MUL {CAR :p} {CDR :p}}}}
{lambda {:n}
        {CDR {{:n ITER.PAIR} {CONS ONE ONE}}}}}
-> ITER

{CHURCH {ITER TWO}} -> 2
{CHURCH {ITER THREE}} -> 6
{CHURCH {ITER FOUR}} -> 24
{CHURCH {ITER FIVE}} -> 120
```

# 2.4. ... to Recurse, Divine »<sup>[8]</sup>

So, we would like to define the factorial using its recursive mathematical definition:

```
fac(n) = 1 if n == 0 else fac(n) = n*fac(n-1)
```

We begin to define a few boolean operators:

Note that TRUE, FALSE, IF are aliases to CAR, CDR, CONS.

Here is the tricky part! We must remember that all expressions except abstractions are evaluated *eagerly*: functions' arguments are *called by value* and not *called by name*. Inside the IF function every arguments are evaluated before the call and this would lead to an *infinite loop* in a recursive process. A workaround is to use abstraction to introduce *manually* some kind of lazyness. This is an answer:

```
def FAC
 {lambda {:n}
  {{lambda {:bool :true :false :n}
   {{{:bool :n}
                              // compute bool
     {IF :true :false}}
                              // choose now
                               // force now
    :n}}
    {lambda {:n} {ISZERO :n}} // delay
    {lambda {:n} {SUCC ZERO}} // delay
    {lambda {:n} {MUL :n {FAC {PRED :n}}}}
    :n
                               // for n
} } }
-> FAC
```

```
{CHURCH {FAC FIVE}}
-> 120
```

Let's introduce some **Y-combinator** making recursive an almost recursive function:

```
{def Y {lambda {:g :n} {:g :g :n}} -> Y

{def IFTHENELSE {lambda {:b :t :f :g :n}
    {{:b :n} {IF :t :f}} :g :n} }

-> IFTHENELSE

{def ALMOST_FAC {lambda {:g :n}
    {IFTHENELSE
    {lambda {:n} {ISZERO :n}}
    {lambda {:g :n} {SUCC ZERO}}
    {lambda {:g :n} {MUL :n {:g :g {PRED :n}}} :g :n }}

-> ALMOST_FAC

{CHURCH {Y ALMOST_FAC FIVE}}
-> 120
```

Let's mix the both:

```
{def YFAC {lambda {:n}
    {{lambda {:g :n} {:g :g :n}}
    {lambda {:g :n}
    {IFTHENELSE
        {lambda {:n} {ISZERO :n}}
        {lambda {:g :n} {SUCC ZERO}}
        {lambda {:g :n} {MUL :n {:g :g {PRED :n}}}
        :g :n}}
        :n}}}
-> YFAC

{CHURCH {YFAC FIVE}}
-> 120
```

Throwing away the name, let's define and immediately call the lambda on the value 5:

```
{CHURCH
{{lambda {:n} {{lambda {:g :n} {:g :g :n}}}
    {lambda {:g :n}
    {IFTHENELSE
     {lambda {:n} {ISZERO :n}}
    {lambda {:g :n} {SUCC ZERO}}
    {lambda {:g :n} {MUL :n {:g :g {PRED :n}}}}
    :g :n} :n} FIVE}}
-> 120
```

Finally, let's replace all constants by their lambda based values to get a pure  $\lambda$ -calculus expression made of words, abstractions and applications:

```
{CHURCH {{lambda {:n} {{lambda {:g :n} {:g :g
:n}} {lambda {:g :n} {{lambda {:b :t :f :g :n}
{{{:b :n} {{lambda {:x :y :z} {:z :x :y}} :t
:f}} :g :n} {{lambda {:n} {{lambda {:n} {:n
{lambda {:x} {lambda {:z} {:z {lambda {:x :y}
:y}}}} {lambda {:z} {:z {lambda {:x :y}
:y}}}};
:n} {{lambda {:g :n} {{lambda {:n :f :x} {:f
{{:n :f} :x}}} {lambda {:f :x :x}}} {lambda {:g
:n} {{lambda {:n :m :f} {:m {:n :f}}} :n {:g :g
{{lambda {:n} {{lambda {:z} {:z {lambda {:x :y}}
:x}}} {{:x :y}} {{lambda {:z} {:z {lambda {:x :y}}
:x}}} {{:x :y}} {{lambda {:z} {:z {lambda {:x :y}}
:x}}};
} {{lambda {:n :f :x} {:f {{:n :f} :x}}}}
{{lambda {:z} {:z {lambda {:x :y}}
:x}}}
{{lambda {:z} {:z {lambda {:x :y}}
:p} {{lambda {:n :f :x} {:f {{:n :f} :x}}}}
{{lambda {:z} {:z {lambda {:x :y} :y}}}}
}
```

```
{{lambda {:x :y :z} {:z :x :y}} {lambda {:f :x} :x} {lambda {:f :x} :x}}}} :n}}} ;g :n}} ;g :n}}} {
{lambda {:f :x} {:f {:f {:f {:f :x}}}}}}
-> 120
```

Concluding this section, using nothing but words and text replacement processes, forgetting limitations of Javascript numbers and so theoretically regardless of its size and with a total precision, we could compute the factorial of any natural number. But if computing 5! is rather fast, about 50ms on a recent computer, computing 50! would still be too long! It's time to remember that we can use the power of modern browsers to make things easier and much more faster!

## 3. {LAMBDA TALK}

In this section Church numbers and their related operators built as user defined functions are *forgotten* and replaced by primitive functions built on the browser's foundations. We use Javascript's numbers, Math operators and functions, HTML tags, CSS rules, SVG and more. We add *aggregate datas* like pairs, lists, arrays and some others specific to the wiki context. We add new special forms, [if, let, quote, macro]. Note that there is no set! special form, {lambda talk} is purely functional. This is the current dictionary:

**DICTionary:** (249) [ debug, lib, eval, apply, <, >, <=, >=, =, not, or, and, +, -, \*, /, %, abs, acos, asin, atan, ceil, cos, exp, floor, pow, log, random, round, sin, sqrt, tan, min, max, PI, E, date, serie, map, reduce, equal?, empty?, chars, charAt, substring, length, first, rest, last, nth, replace, array.new, array, array.disp, array.array?, array.null?, array.length, array.item, array.first, array.last, array.rest, array.slice, array.concat, array.set!, array.push!, array.pop!, array.unshift!, array.shift!, array.reverse!, array.sort!, cons, cons?, car, cdr, cons.disp, list.new, list, list.disp, list.null?, list.length, list.reverse, list.first, list.butfirst, list.last, list.butlast, @, div, span, a, ul, ol, li, dl, dt, dd, table, tr, td, h1, h2, h3, h4, h5, h6, p, b, i, u, center, hr, blockquote, sup, sub, del, code, img, pre, textarea, canvas, audio, video, source, select, option, svg, line, rect, circle, ellipse, polygon, polyline, path, text, g, mpath, use, textPath, pattern, image, clipPath, defs, animate, set, animateMotion, animateTransform, br, mailto, back, hide, input, script, style, iframe, drag, note, note\_start, note\_end, show, lightbox, minibox, editable, turtle, forum, lisp, long\_mult, BN.DEC, BN.new, BN.+, BN.-, BN.\*, BN./, BN.%, BN.pow, BN.compare, BN.negate, BN.abs, BN.intPart, BN.valueOf, BN.round, BN.fac, SMART\_ADD, HI, GOOD\_DAY, CONS, CAR, CDR, BAR, ZERO, ONE, TWO, THREE, FOUR, FIVE, CHURCH, SUCC, ADD, MUL, POWER, PRED. PAIR, PRED, ITER. PAIR, ITER, TRUE, FALSE, IF, ISZERO, FAC, Y, IFTHENELSE, ALMOST FAC, YFAC, FACT, TFAC.rec, TFAC, BI.bigint2pol.rec, BI.bigint2pol, BI.pol2bigint.rec, BI.pol2bigint, Bl.simplify.rec, Bl.simplify, Bl.pk, Bl.p+, Bl.p\*, Bl.tfac.r, Bl.tfac, castel.interpol, castel.sub, castel.point, castel.build, svg.dot, p0, p1, p2, p3, red\_curve, green\_curve, QUOTIENT, SIGMA, PAREN, mul, spreadsheet, sheet.new, sheet.input, sheet.output, TITLE, WRAP, ref, back ref, space ]

where can be seen the user defined functions starting at SMART ADD, the first constant created in the quick introduction.

In order to illustrate some of these capabilities we will write effective recursive factorials, compute big numbers, play with tabular data in a spreadsheet, explore intensive computing with javascripts, build regular expressions based macros.

## 3.1. recursion

In the previous section we have seen how tricky it was to write a recursive algorithm. We had to write *manually* a lazy behaviour.

Using the third {if bool then one else two} special form and its built-in *lazy evaluation* the way is opened to efficient recursive algorithms. It's now possible to write the factorial function following its mathematical definition:

Let's write the tail-recursive version:

```
{def TFAC
{def TFAC.rec
    {lambda {:a :n}
        {if {< :n 0}
            then {b n must be positive!}
        else {if {= :n 0} then :a
        else {TFAC.rec {* :a :n} {- :n 1}}}}
{lambda {:n} {TFAC.rec 1 :n}}
-> TFAC

{TFAC 5} -> 120
{TFAC 50} -> 3.0414093201713376e+64
```

The recursive part is called by a *helper function* introducing the accumulator ":a". {lambda talk} doesn't know lexical scoping - the TFAC.rec inner function is global - and this leads to some pollution of the dictionary. The *Y-combinator* mentionned above, *making recursive an almost-recursive function*, will help us to discard this helper function. The *Y-combinator* and the almost-recursive function can be defined and used like this:

Because the *Y-combinator* can be applied to any other almost-recursive function (sharing the same signature, for instance the fibonacci function) we have reduced the pollution but we can do better. Instead of applying the Y combinator to the almost recursive function we can define a function composing both:

```
{def YFAC {lambda {:n}
    {{lambda {:f :a :n}}
    {:f :f :a :n}
    {lambda {:f :a :n}
        {if {< :n 0}
            then {b n must be positive!}
        else {if {= :n 0} then :a
        else {:f :f {* :a :n} {- :n 1}}}} 1 :n}}}</pre>
```

```
-> YFAC

{YFAC 5}
-> 120
{YFAC 50}
-> 3.0414093201713376e+64

{map YFAC {serie 0 20}}
-> 1 1 2 6 24 120 720 5040 40320 362880 3628800 39916800 479001600 6227020800 87178291200 1307674368000 20922789888000 355687428096000 6402373705728000 121645100408832000 2432902008176640000
```

It's fast but there is a last point to fix: {FAC 50}, {TFAC 50} and {YFAC 50} return a rounded value 3.0414093201713376e+64 which is obviously not the exact value. We must go a little further and build some tools capable of processing big numbers.

# 3.2. big numbers

The way the Javascript Math object is implemented puts the limit of natural numbers to  $2^{54}$ . Beyond this limit last digits are rounded to zeros, for instance, as we will demonstrate later, the four last digits of  $2^{64} = \{\text{pow 2 64}\} = 18446744073709552000$  should be 1616 and are rounded to 2000. And beyond  $2^{69}$  natural numbers are replaced by float numbers with a maximum of 15 valid digits. In order to overcome this limitation we come back to the definition of a natural number: A natural number  $a_0a_1...a_n$  is the value of a polynomial  $\sum_{i=0}^{n} a_i x^i$  for some value of x, called the base. For instance  $12345 = 1*10^4 + 2*10^3 + 3*10^2 + 4*10^1 + 5*10^0$ . We build a set of user defined functions defining addition, multiplication of polynomials and some helper functions:

```
{def BI.bigint2pol
 {def BI.bigint2pol.rec
  {lambda {:n :p :i}
   {if {< :i 0}
   then :p
    else {BI.bigint2pol.rec
          :n
          {cons {charAt :i :n} :p} {- :i 1}}}}
 {lambda {:n}
  {BI.bigint2pol.rec :n nil {- {chars :n} 1}}}
-> BI.bigint2pol
{def BI.pol2bigint
 {def BI.pol2bigint.rec
  {lambda {:p :n}
   {if {equal? :p nil}
    then :n
   else {BI.pol2bigint.rec
           {cdr :p} {car :p}:n}}}
 {lambda {:p}
  {let { (:q {list.reverse :p}} }
   {BI.pol2bigint.rec {cdr :q} {car :q}}}}
-> BI.pol2bigint
{def BI.simplify
 {def BI.simplify.rec
  {lambda {:p :q :r}
   {if {and {equal? :p nil} {= :r 0}}
   then :q
   else {if {equal? :p nil} then {cons :r :q}
    else {BI.simplify.rec
          {cdr :p}
          {cons {+ {% {car :p} 10} :r} :q}
          {floor {/ {car :p} 10}} }}}
{lambda {:p}
```

```
{BI.simplify.rec {list.reverse :p} nil 0}}}
-> BI.simplify
{def BI.pk
 {lambda {:k :p}
  {if {equal? :p nil}
   then nil
   else {cons {* :k {car :p}}}
              {BI.pk :k {cdr :p}}} }}
-> BI.pk
{def BI.p+
 {lambda {:p1 :p2}
  {if {and {equal? :p1 nil} {equal? :p2 nil}}
   then nil
   else {if {equal? :p1 nil} then :p2
   else {if {equal? :p2 nil} then :p1
   else {cons {+ {car :p1} {car :p2}}
              {BI.p+ {cdr :p1} {cdr :p2} }}}}}
-> BI.p+
{def BI.p*
 {lambda {:p1 :p2}
  {if {or {equal? :p1 nil} {equal? :p2 nil}}
   then nil
   else {if {not {cons? :p1}}}
   then {BI.pk :p1 :p2}
   else {BI.p+ {BI.pk {car :p1} :p2}
               {cons 0 {BI.p* {cdr :p1}}
:p2}}}}}}
-> BI.p*
```

On this set of functions we can now compute the factorial of natural numbers of any size with an exact precision:

We finally reached the goal: with the subset of special forms [lambda, def, if], the cons and lists structures, a few Math operators and without any external library we have computed the exact value of **50!** But we need to go a little further.

## 3.3. when {lambda talk} calls Javascript

Until now user defined functions were exclusively created in the {lambda talk} syntax. With a large speed penalty when comes intensive computation. We can write new functions in the Javascript syntax inside {script ... Javascript code ...} forms.

When a set of user defined functions written in {lambda talk} or Javascript syntaxes increazes in size, it's better to externalize it in some other wiki page used as a **library** and called via a (require library\_name). This helps {lambda talk} to stay minimal, coherent, orthogonal, and any user to create, add and maintain his

specific **library**. In the following we illustrate some of these capabilities.

## *3.3.1. the lib\_bignum library*

Jonas Raoni Soares Silva<sup>[9]</sup> has written a small (150 lines) and smart Javascript library, BigNumber, ready to be called via {lambda talk} wrapping functions, everything being stored in another wiki page, lib\_bignum. We just write the factorial function using the multiplicate operator BN.\* redefined for big numbers:

```
{def BN.fac
  {lambda {:n}
    {if {= :n 0}
        then 1
        else {BN.* :n {BN.fac {- :n 1}}}}}}
-> BN.fac
```

and call it on the number 50:

```
{BN.fac 50}
-> 304140932017133780436126081660647
68844377641568960512000000000000
```

Obviously it's the fastest and best choice!

**Note:** Using this library, we can control that the value of  $2^{64}$  given by the Javascript Math object,  $\{pow \ 2 \ 64\} = 18446744073709552000$  is not its exact value  $\{BN.pow \ 2 \ 64\} = 18446744073709551616!$ 

## *3.3.2. the lib\_spreadsheet library*

A spreadsheet is a good illustration of functional languages, (Simon Peyton-Jones [10]). A spreadsheet is an interactive computer application for organization, analysis and storage of data in tabular form. The basic idea is that each cell contains the input-words and expressions - and displays the output. Calling a set of Javascript and {lambda talk} functions stored in a wiki page, lib\_spreadsheet, and writing {spreadsheet 4 5} displays the following table of 5 rows and 4 columns of editable cells:

Editing cell L5C4:			
$\{+ \{U -3 \ 0\} \{U -2 \ 0\} \{U -1 \ 0\}\}$			//
NAME	QUANT	<b>UNIT PRICE</b>	PRICE
Item 1	10	2.1	21
Item 2	20	3.2	64
Item 3	30	4.3	129
		TOTAL	214
		PRICE	

[local storage]

Two specific functions are added for linking cells:

- {LC i j} returns the value of the cell L<sub>i</sub>C<sub>j</sub> as an absolute reference,
- {IJ i j} returns the value of the cell L<sub>[i]</sub>C<sub>[j]</sub> as a *relative* reference. For instance writing {IJ -1 -1} in L2C2 will return the value of L1C1.

Datas are stored in the browser's *localStorage*. Let's test: click on the [local storage] button, copy the code in the frame below, paste

it in the local storage frame, click on the **editor -> storage** button, confirm the action and analyze the spreadsheet's cells.

```
["{b NAME}","{b QUANT}","{b UNIT PRICE}","{b PRICE}","Item 1","10","2.1","{* {IJ 0 -2} {IJ 0 -1}}","Item 2","20","3.2","{* {IJ 0 -2} {IJ 0 -1}}","Item 3","30","4.3","{* {IJ 0 -2} {IJ 0 -1}}","","","{b TOTAL PRICE}","{+ {IJ -3 0} {IJ -2 0} {IJ -1 0}}","4"]
```

## 3.3.3. graphics

The **de Casteljau** recursive algorithm<sup>[11]</sup> allows drawing Bezier curves of any degree, i.e controlled by any number of points. Defining points as pairs and control polylines as lists, we build a small set of {lambda talk} user defined functions feeding the points attributes of SVG polylines:

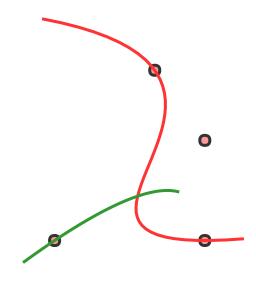

```
{def castel.interpol {lambda {:p0 :p1 :t}
{cons {+ {* {car :p0} {- 1 :t}}}
       {* {car :p1} :t}}
{+ {* {cdr :p0} {- 1 :t}}
          {* {cdr :p1} :t}}
-> castel.interpol
{def castel.sub {lambda {:1 :t}
 {if {equal? {cdr :l} nil}
  then nil
  else {cons
   {castel.interpol {car :1} {car {cdr :1}} :t}
   {castel.sub {cdr :1} :t}}}}
-> castel.sub
{def castel.point {lambda {:1 :t}
{if {equal? {cdr :l} nil}
  then {car {car :1}} {cdr {car :1}}
 else {castel.point {castel.sub :1 :t} :t}}}
-> castel.point
{def castel.build {lambda {:1 :a :b :d}
{map {castel.point :l} {serie :a :b :d}}}
-> castel.build
{def svg.dot {lambda {:p}}
{circle {@ cx="{car :p}" cy="{cdr :p}" r="5"
            stroke="black" stroke-width="3"
            fill="rgba(255,0,0,0.5)"}}}
-> svg.dot
```

#### For instance the following code:

```
{def p0 {cons 150 80}} -> p0
{def p1 {cons 200 150}} -> p1
{def p2 {cons 50 250}} -> p2
{def p3 {cons 200 250}} -> p3
{def red_curve {castel.build
    {list {p0} {p1} {p2} {p3}}
    -0.3 1.1 {pow 2 -5}}}
-> red_curve
{def green_curve {castel.build
    {list {p2} {p1} {p3}}
    -0.1 0.6 {pow 2 -5}}}
-> green_curve
{svg.dot {p0}}
{svg.dot {p1}}
{svg.dot {p2}}
{svg.dot {p2}}
{svg.dot {p3}}
{polyline {@ points="{red_curve}"
```

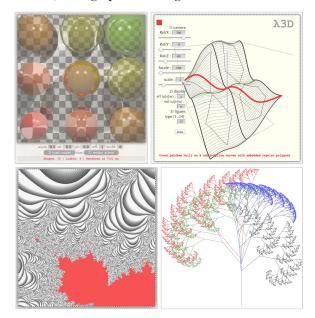

```
stroke="red" fill="transparent"
stroke-width="3"}}
{polyline {@ points="{green_curve}"
stroke="green" fill="transparent"
stroke-width="3"}}
```

draws a cute  $\lambda$  in an SVG frame:

## 3.3.4. intensive computing

For intensive computing, it's obviously more efficient to call the underlying language, Javascript. These are screenshots of wiki pages dedicated to ray-tracing, [12] curved shapes modeling [13], fractals [14], turtle graphics drawing [15].

3.3.5. mathML

$$i\hbar\frac{\partial\psi}{\partial t}(x,t) = \left(mc^2\alpha_O - i\hbar c\sum_{j=1}^3\alpha_j\frac{\partial}{\partial x_j}\right)\psi(x,t)$$

The Dirac equation in the form originally proposed by Dirac

{lambda talk} forgets the **MathML** markup set which is not implemented in Google Chrome<sup>[16]</sup>. A set of functions, exclusively built on standard HTML and CSS rules, can be defined to render Math Symbols. For instance the above **Dirac equation** is not a picture but the result of the code below:

```
i{del h}{QUOTIENT 30 \partial \psi \partial t}(x,t) = {PAREN 3 (} mc{sup 2}\alpha{sub 0} - i{del h}c {SIGMA 30 j=1 3}\alpha{sub j}{QUOTIENT 30 \partial \alpha{sub j}} {PAREN 3 )} \psi(x,t)
```

calling three user defined {lambda talk} functions:

```
{def QUOTIENT
 {lambda {:s :num :denom}
 {table
   {@ style="width::spx;
             display:inline-block;
             vertical-align:middle;
             text-align:center;"}
 {tr {td {@ style="border:0 solid;
                  border-bottom:1px
solid;"}:num}}
{tr {td {@ style="border:0 solid;"}:denom}} }}}
-> QUOTIENT
{def SIGMA
{lambda {:s :one :two}
  {table
   {@ style="width::spx;
            display:inline-block;
             vertical-align:middle;
            text-align:center;"}
 {tr {td {@ style="border:0 solid;"}:two}}
 {tr {td {@ style="border:0 solid;
                   font-size:2em;
                   line-height:0.7em;"\Sigma}
{tr {td {@ style="border:0 solid;"}:one}} }}
-> SIGMA
def PAREN
 {lambda {:s :p}
  {span {@ style="font:normal :sem arial;
                 vertical-align:-0.15em;"}:p}}
-> PAREN
```

## 3.4. what about macros?

A language without macros is not a "true" language, isnt'it? {lambda talk} macros bring (a little bit of) the power of regular expressions directly in the language.

#### 3.4.1. make it variadic

{lambda talk} comes with some variadic primitives, for instance [+, -, \*, /, list, ...]. But at first sight, user functions can't be defined variadic, for instance:

In order to make mul variadic we glue values in a list and define an helper function, variadic:

But it's ugly and doesn't follow a standard call. We can do better using a macro:

```
1) defining:
{macro {mul* (.*?)}
    to {variadic mul {list €1}}}
2) using:
{mul* 1 2 3 4 5}
-> 120
```

Now mul\* is a variadic function which can be used as any other primitive or user function, except that it's not a first class function, as in most Lisps.

## 3.4.2. titles, paragraphs & links

As a last example, {lambda talk} comes with a predefined small set of macros allowing writing without curly braces titles, paragraphs, list items, links:

```
_ h1 TITLE ¬
    stands for: {h1 TITLE}

_p Some paragraph ... ¬
    stands for: {p Some paragraph ...}

[[PIXAR|http://www.pixar.com/]]
    stands for: {a {@}
href="http://www.pixar.com/"}PIXAR}

[[sandbox]]
    stands for: {a {@ href="?}
view=sandbox"}sandbox}
```

These simplified alternatives, avoiding curly braces as much as possible, are fully used in the current document.

## **CONCLUSION**

{lambda talk} takes benefit from the extraordinary power of modern web browsers, simply adding a coherent and unique syntax, without re-inventing the wheel, just using existing tools, HTML/CSS, the DOM and Javascript. Standing on the shoulders of such giants, {lambda talk} can be built as a minimal regexp based implementation of the  $\lambda$ -calculus, where the repeated substitutions inside the code string overcomes limitations of regular language, where the lack of closure is balanced by the built-in partial application, where a dictionary initially empty can be extended "inline" via user defined libraries. More can be seen in the following APPENDICE.

The {lambda way} project is a thin overlay - under 100kb - built upon any modern browser, proposing a small interactive

development environment, {lambda tank}, and a coherent language, {lambda talk}, without any external dependencies and thereby easy to download and install on a web account provider running PHP. From any web browser on any system, complex web pages can be created, enriched, structured and (algorithms) tested in real time on the web. The current document has been created in this wiki page,

http://lambdaway.free.fr/lambdaway/? view=oxford then directly printed from the browser as a PDF document.

Alain Marty, 2017/06/12

### **APPENDICE**

In this section we present the minimal set of JavaScript functions necessary and sufficient to implement abstractions, applications, definitions and the ifthenelse control structure.

### 1. evaluation

Working on the client side the {lambda talk} evaluator is a Javascript IIFE (Immediately Invoked Function Expression), LAMBDATALK, returning the public function eval(). This function is called at every keyboard entry and replaces the string code by its evaluation, without building any Abstract Syntaxic Tree.

```
var LAMBDATALK = (function() {
var eval = function(str) {
   str = pre_processing(str);
   str = abstract_lambdas(str); // abstraction
   str = abstract_defs(str); // abstraction
   // some other special forms
   str = eval_forms(str); // application
   str = post_processing(str);
   return str;
};
return {eval:eval}
})();
```

## 2. application

In a single loop, using a single regular expression<sup>[17]</sup>, simple forms {first rest} are recursively evaluated from the leaves to the root and replaced by words. The evaluator stops when simple forms are reduced to a sequence of words, actually a valid **HTML code** sent to the browser's engine for the final evaluation and display. Using a regular expression based window, the evaluator literally loops over the code string, skips the words and progressively replaces in situ forms by words. The repeated substitutions inside the code string overcomes limitations of regular language. A kind of Turing machine<sup>[18]</sup> ...

```
var eval_forms = function( str ) {
  while (str !=
  (str=str.replace(leaf,eval_leaf)))
    ; // does nothing!
  return str
};
var leaf = /\{([^\s{}]*)(?:[\s]*)([^{\}]*)\}/g;
var eval_leaf = function(_,f,r) {
  return (DICT.hasOwnProperty(f)) ?
```

```
DICT[f].apply(null,[r]) : '('+f+'
'+r+')'
};
var DICT = {}; // initially empty
```

#### 3. abstraction

Special forms {lambda {arg\*} body} are matched and evaluated **before** simple forms and replaced by a reference to an anonymous function added to the dictionary. The following code demonstrates that:

- 1) lambdas are first class functions,
- 2) lambdas accept partial function application, when called with a number of values lesser than their arity, they memorize the given values and return a lambda waiting for the rest,
- 3) lambdas don't create closures, inner lambdas have no access to outer lambdas' arguments, there is no lexical scoping, no environment, no free variables. Like mathematical functions lambdas are pure black boxes.

```
var abstract lambdas = function(str) {
  while (str!== (str=
   form_replace(str,'{lambda',
abstract lambda)));
 return str
var abstract_lambda = function(s){
s = abstract lambdas( s ); // nested lambdas
 var index = \overline{s.indexOf(')}'),
     args = supertrim(s.substring(1,
index)).split(' '),
      body = s.substring(index+2).trim(),
      name = ' LAMB ' + LAMB num++,
     reg_args = [];
 for (var i=0; i < args.length; i++)
 reg args[i] = RegExp( args[i], 'g');
body = abstract ifs( body ); // {ifthenelse}
 DICT[name] = function() {
  var vals =
      supertrim(arguments[0]).split(' ');
  return function (bod) {
   bod = ifthenelse( bod, reg args, vals );
   if (vals.length < args.length) {
    for (var i=0; i < vals.length; i++)</pre>
    bod = bod.replace(reg args[i], vals[i]);
    var _args=args.slice(vals.length).join(' ');
   bod = '{' + args + '} ' + bod;
   bod = abstract lambda(bod);
                                    // return a
lambda
   } else {
                               // return a form
    for (var i=0; i < args.length; i++)
     bod = bod.replace(reg args[i], vals[i]);
   return bod;
  } (body);
 };
return name;
var form replace = function(str,sym,func,flag){
 sym += ' ';
  var s = catch form(sym, str);
 return (s==='none')?
     str:str.replace(sym+s+')',func(s,flag))
var catch form = function( symbol, str ) {
  var start = str.indexOf( symbol );
  if (start == -1) return 'none';
 var d0, d1, d2;
```

## 4. definition

Special forms {def name expression} are matched and evaluated **before** simple forms and replaced by name as a reference to expression added to the dictionary.

```
var abstract defs = function(str, flag) {
  while (str !== (str =
   form replace ( str, '{def', abstract def,
flag )));
 return str
var abstract def = function (s, flag) {
  flag = (flag === undefined)? true : false;
  s = abstract_defs( s, false );
 var index = s.search(/\s/), // match spaces &
      name = s.substring(0, index).trim(),
     body = s.substring(index).trim();
  if (body.substring(0,6) === ' LAMB ') {
    DICT[name] = DICT[body];
    delete DICT[body];
  } else {
    body = eval forms(body);
     DICT[name] = function() { return body };
 return (flag)? name : '';
```

## 5. ifthenelse

Special forms {if bool then one else two} are matched in lambda's bodies and replaced by the reference to an array [bool, one, two]. When the lambda is called with some values, one or two is returned according to the **bool** value.

```
var abstract ifs = function(str) {
 while (str !== (str =
   form replace( str, '(if', abstract if )));
 return str
};
var abstract if = function(s){
 s = eval_ifs(s);
 var name = ' COND ' + COND num++;
 var index1 = s.indexOf( 'then'),
     index2 = s.indexOf( 'else'),
           = s.substring(0,index1).trim(),
     bool
     one
s.substring(index1+5,index2).trim(),
     two
           = s.substring(index2+5).trim();
 COND[name] = [bool,one,two];
 return name;
var eval ifs = function(bod, reg args, vals) {
  var m = bod.match( / COND \d+/ );
  if (m === null) {
    return bod
```

```
} else {
    var name = m[0];
    var cond = COND[name];
    if (cond === undefined) return bod;
    var bool=cond[0], one=cond[1], two=cond[2];
    if (reg args !== undefined) {
     for (var i=0; i < vals.length; i++) {
      bool = bool.replace(reg args[i],
vals[i]);
       one = one.replace(reg args[i], vals[i]);
       two = two.replace(reg_args[i], vals[i]);
     var boolval = (eval_forms(bool) === 'true')?
                   one : two;
    bod = bod.replace( name, boolval );
     return eval ifs( bod, reg args, vals )
};
```
